ABSTRACT .Briefly generalized are the findings of tests
 with fertilization of potatoes at the
 Kuznetskaya agricultural experimental station
 during the period from 1938 to 1946; also give
 are the results of tests in recent years. In
 the average during the first 7 years of observa-
 tions, the greatest gain (70 centners/
 hectare) of tuber crop yield was obtained from
 joint placement of nitrogen and phosphorus
 fertilizers, in case of 131.6 centners/hectare

TITLE: Reaction of GaS with gaseous ammonia at high temperatures

SOURCE: Zhurnal neorganicheskoy khimii, v. 10, no. 6, 1965, 1507-1508

TOPIC TAGS: ²⁷gallium nitride, ²⁷gallium sulfide, ²⁷ammonia, ²⁷semiconductor

ABSTRACT: The emissive properties of the semiconductor gallium nitride (GaN) are determined to a large extent by the temperature at which it is synthesized. In this connection, the authors propose a method for preparing GaN at relatively low temperatures (800 and 900C) by reacting GaS with dry ammonia, the reaction is

The products were stable in air at room temperature; at about 1000C, they formed gallium oxide. They did not react with water, hydrochloric or nitric acid, but dissolved on heating in concentrated alkalis and after prolonged boiling in dilute sulfuric acid. In order to make sure that the synthesized compound was gallium nitride, not gallium amide (GaNH), GaN was synthesized by the method of H. Hahn and R. Juza (Z. anorg. Chem., 244, 111, 1940).

TITLE: Synthesis and Isomerization of Enol Acetates of β -Furanidons
(Sintez i izomerizatsiya enolatsetatov β -furanidonov)

PERIODICAL: Doklady Akademii Nauk SSSR, 1957, Vol. 114, Nr 2, pp. 527-530
(USSR)

ABSTRACT: The derivatives of the enolic form of tetrahydrofuranon-3
(β -furanidon) and of its homologues have hardly been investigated at all. The authors of the paper under review, in order to produce the acetylic derivatives of the enolic form, used such ketones of the β -furanidon series in which only one single methylene group stands in the α -position with respect to the carbonyl group. This made it possible to obtain only one enolic acetate with a position of the double bond that was known in advance. Isopropenylacetate was used as acetylating substance. So far, this type of the interesting β -furanidon derivatives has not been described.

Card 1/3

Synthesis and Isomerization of Enol Acetates of β -Furanidons

of these enolic acetates with respect to halogenation and isomerization. At chlorine blowing through 2,2,5,5-tetramethylfuranidon-3-enolacetate, or through its solution in chloroform or absolute ether, there is produced at -5° a monochlorine-ketone of the furanidine series, i.e. 4-chlorine-2,2,5,5-tetramethylfuranidon-3. This reaction is of fundamental importance, but it has no preparational significance. One of the most interesting reactions is the isomerization of the thermal or catalytic enolacetate-ketone into β -diketones. If triborofluoride is let through cooled enolic acetate at -40 to -20° , no isomerization takes place. At -10 to -5° , on the other hand, after a certain period of induction a turbulent reaction takes place as well as a total resinification of the reaction mixture. If the same enolic acetate is let through a glass tube, which is filled with wadding of glass and heated up to a temperature of 500° (but not below) then an isomerization into 4-acetyl-2,2,5,5-tetramethylfuranidon-3 takes place. At higher temperatures the yield decreases from 36.5 % to 5 - 10 %. As a matter of fact, it is split into a ketone and a ketene. The production of a cupric salt and of the derivatives of the 4-acetyl-2,2,5,5-tetramethyl-

Card 2/3

- Synthesis and Isomerization of Enol Acetates of β -Furanidons

furanidon-3 as well as an intense violet coloring by solution of ferric chloride confirm its structure. The spectrum of absorption of this cupric salt as analogous to the spectrum of absorption of the cupric salt of acetylacetone, which is one of the characteristic β -diketones. The experimental part of the paper under review describes in detail the reactions together with yields, constants and methods. There are 6 references, 2 of which are Soviet.

ORIG. PUB. : Dokl. Mosk. s.-kh. akad. ts. K. A. Timiryazeva, 1957,
vyp. 31, 162-166
ABSTRACT : The feasibility of using dry serums in diagnosis of cer-
tain bacterial and virus diseases was studied. Prepared
and studied were serums specific against *Pseudomonas*
turfaciens, *Xanthomonas vesicatorum* and *B. syringae*,
the virus of tobacco mosaic and against X virus of potato.
Dilution of anti-bacterial serums was 1:50; dilution of
anti-virus ones - 1:8. Serums were diluted with distilled
water, physiological solution, 1% glucose, 0.1% gelatine
plus 1% glucose. The diluted serums were applied onto
photographic film from which emulsion had been washed off.

SOURCE: IVUZ. Energetika, no. 6, 1966, 128

TOPIC TAGS: electric engineering personnel, academic personnel

ABSTRACT: L. N. Baptidanov died January 13, 1966. His working life was primarily dedicated to training of electrical engineering specialists. Soon after graduating from the Electrical Industrial Faculty of the Moscow Institute of the National Economy, Baptidanov began teaching at the Moscow Power Technical School. In 1934, Baptidanov began teaching at the All Union Correspondence Industrial Institute, then in 1946 he shifted to the All Union Industrial Academy of Machine Building, where he worked in the chair of electrical power stations. He was responsible for the creation of a model electrical station in the electrical stations chair of the Moscow Power Institute. Baptidanov was also very active as an author, writing such works as "Industrial Enterprise Substations", "Electrical Equipment of Electrical Stations and Substations", etc. From 1943 to 1946, Baptidanov worked as the Scientific editor for Electrical engineering at the State Power Literature Publishing House. The non-Newton state. XIX. Concentration dependence of the viscosity of liquids. J. Tech. Phys. (U.S.S.R.)

Vol. 1, 1934, pp. 2-9

Abstracted in: Chem. Abstr., Vol. 33, 1935³

The law of viscosity is plotted as a function of time for many different solutions: ethers, alcohols, glycerol, urea, dioxane, etc., also SiO₂, halter salts, halter esters, etc. All curves have a similar trend; they are flat for low dilutions, steep for high dilutions. In a complete system the viscosity curve of the liquid drops (as a temp. coeff.) to a viscosity of 10^{-1} to 10^{-2} dynes/cm² at the crit. temp., reverses to the opposite direction (i.e., temp. coeff. of viscosity is $\alpha > 0$). It is believed possible to develop a general theory for all liquids.

PHASE I BOOK EXPLOITATION SOV/1552

Kuvshinskiy, Vladimir Vladimirovich

Frezerovaniye (Milling Operations) 2nd ed., rev. and enl.
 Moscow, Mashgiz, 1958. 408 p. 45,000 copies printed.

Reviewer: V. T. Poluyanov, Engineer; Executive Ed. (Ural-Siberian Division, Mashgiz): L.A. Kon'shina, Engineer;
 Tech. Ed.: N.A. Dugina.

PURPOSE: The purpose of this book is to raise the qualifications of milling machine operators, and to improve their theoretical knowledge of the fundamentals of milling operations.

COVERAGE: The book deals with the basic principles and theories of milling operation and the tools and machinery used in the Soviet machine industry. The elements of cutting tools and principles of design are explained. Modern milling machines are reviewed and illustrated. The proper use of various types of machinery and the ways and means of increasing

Card 1/8

Milling Operations

 PROCESSES AND PROPERTIES 1111
 Research on the amorphous state. III. Dielectric constants of amorphous substances in the softening interval. P. P. Kobeko and E. Kuyshinskii. *Physik. Z. Sowjetunion* 4, (84) 04 (1953); cf. preceding abstr.—Brucine, phenolphthalein, cane sugar and 90% EtOH were studied in the temp. interval between the m. p. and the temp. of vitrification (T_g). Changes in the static and dynamic polarization constants are accord. with a change in the relaxation time, and with a change in the no. of rotating dipoles. This is explained by the loss in rotary motion of the mol. as T_g is approached. A departure from the Debye model above T_g is due to assocn. Below T_g , the regular variation of the dielec. const. with frequency, which is analogous to that of compact cryst. bodies, cannot be connected with the internal friction. Dielec. loss below T_g is very low. Cond. is unaffected in this temp. region. In the region in which the static dielec. const. changed rapidly the potential distribution remained linear. IV. Electrical conductivity of mixtures in the softening interval. P. P. Kobeko and I. O. Nelidov. *Ibid.* 6(5) 702.—In amorphous substances and mixts., the elec. cond. and the temp. T are connected by the equation $\log \sigma = (A - K) + (KT_g/T)$, or $\sigma = A e^{B/T}$, where σ is the resistance, T_g is the temp. of vitrification, and A , B and K are const. Values of T_g , A , B and K are given for EtOH, glycerol, citric acid, sugar; molar mixts. of glycerol with EtOH, glycerol-citric acid and glycerol-sugar wds. 1 mol. of glycerol with 2 mola. EtOH; and for a mixt. of 3 components. The log σ plotted against $(1/T_g - 1/T)10^3$ is linear for values of the second term between 0 and 1.2. The T_g of a mixt.

lies between that of its components. V. Relation between the temperature coefficient of the electrical conductivity and the viscosity in amorphous substances. *Ibid.* 7(1) 11.—The relation between viscosity η and temp., $\log \eta = A' + B'/T$, is linear and is similar to the relation between elec. cond. and temp. Values of T_g , B and B' are given for 94% EtOH, PrOH, lutidine, 1:1 and 1:2 molar mixts. of glycerol and EtOH, tributyrin, citric acid, glycerol, glycerol-citric acid and glycerol-sugar wds. triacetyl, Rochelle salts, betul, piperine, sugar, sugar + 10% H₂O, rosin, salicin, brucine and phenolphthalein
 (Gerald M. Petty)

46. Elasticity of Amorphous Bodies. P. Kobeko, E. Kurshinskij and G. Gurevich. *Techn. Phys. U.S.S.R.* 4, 8, pp. 623-637, 1937. In English.—A notion is introduced of two components of reversible deformation: initial elastic or acoustic deformation and highly elastic deformation. Total mechanical deformation of amorphous bodies is composed of three independent components: the elastic initial deformation, resilient highly-elastic deformation and inelastic plastic deformation. The initial modulus of shearing stresses in amorphous bodies is large. For phenol-phthalein, hard rubber and soft rubber it is equal to 3×10^8 kg/cm², and to 10^8 kg/cm² for rosin. The total modulus is many times less than the initial one. For soft rubber it is equal to 6 kg/cm², for hard rubber—30 kg/cm², for phenol-phthalein—2500 kg/cm². The setting-in time of highly elastic deformation drops very sharply with increasing temperature. Soft rubber and hard rubber are highly elastic at high temperatures as well as at low temperatures. Cooling produces only a drop in the velocity of setting-in of the highly-elastic deformation, but the limiting magnitude of deformation does not change. The hardening of soft rubber and hard rubber takes place not by jumps, but gradually as the temperature goes down, and is similar to the process of turning into glass of monomeric bodies. The manifestation of highly elastic properties may take place at greatly differing viscosities. In polymers the viscosity in the softening interval is very large compared with that of monomeric materials. AUTOMOS.

PROCESSES AND PROPERTIES INDEX

The amorphous state. III Dielectric relaxation in amorphous phenolphthalein. K. V. Kuybyshev and P. P. Kobzarev, *J. Tech. Phys.* (U.S.S.R.) 8, 1718 (1938); *ibid.*, 22, 1935. A no. of deformation processes in liquids are studied. In amorphous phenolphthalein (M.M. also discuss) ϵ'' measured in the interval 75-110° changes with time in accordance with the equation $\epsilon'' = \epsilon''_0 - (\epsilon''_0 - \epsilon''_1)/(1 + t/\tau)^n$. For $\ln \tau_0 = 20$; $n = 2.2$; $n = 0.25-0.4$, depending on the temp. has the same proportionate effect on the rate of elastic deformation $\dot{\epsilon}$, and the rate of dielec. relaxation τ_0 , sp. resistance ρ and viscosity η , which indicates that $\dot{\epsilon}$ is monomeric. The closeness in the values of τ_0 and η indicates that dielec. relaxation and elasticity are closely assocd. in liquids.

KUVSCHINSKI, A. W.

AMORPHOUS STATE. XVIII. ELECTRICAL CONDUCTIVITY OF SUBSTANCES IN THE AMORPHOUS AND CRYSTALLINE STATES. P. P. Kobeko, E. W. Kuvshinski, and N. I. Schischkin (J. Physics U.S.S.R., 1940, 3, 287-296). -- The variation of sp. resistance (ρ) with temp. (T) of borax, Rochelle salt, and LiOAc has been determined for the substances in the amorphous and cryst. states. For the melts of these substances the portion of the function $\log \rho = f(1/T)$ is not linear. For substances in the vitreous state, i.e., considerably supercooled liquid, the relation is linear at low temp. The coeff. B in the expression $\log \rho = A + B/T$ is almost the same for the above substances in the cryst. and vitreous states. The connexion between these results and X-ray structure is considered, and it is shown that Zachariasen's view (A., 1933, 12, 1107), that the arrangement of mols. in the lattices of silicate and borate glasses is the same as in the cryst. state, may be extended to all supercooled systems irrespective of their composition. Since B does not alter, any considerable change of the structure of a liquid with temp. is not possible.

Temperature dependence of the viscosity of liquids

P. P. Kizelko, U. V. Kuryshinskii, and N. I. Shishkin (Leningrad Phys. Tech. Inst.); *Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk, Inst. Mikhonovdeniya, Savskhoye po Vysshosti Zhidkosti i Kollid. Rastvor. (Conf. on Viscosity of Liquids and Colloidal Solns.)* 2, 71 (1964); *U.S.S.R. J. Chem. Phys.* - The currently admitted linear dependence of $\log \eta$ (viscosity) on $1/T$ (abs. temp.), of the form $\log \eta = A + U/RT$, requires that the quantities A and U be const. over the whole temp. interval. Admission of a thermal variability of U makes a comparison of the underlying theories with exptl. data impossible. Curves of $\log \eta$ in terms of $1/T$, over as wide a temp. interval as is available, were constructed for a series of substances, of widely different nature: diethyl ether, ethyl ak., propyl ak., isobutyl ak., glycerol, rosin, HCl, H₂SO₄, H₃PO₄, H₂O, silicate glass, SO₂, BCl₃, LiNO₃, NaCl, Cd, Sn, Hg, air. The graph shows a divergent fan of curves, somewhat shifted relative to one another. The curves are steeper the higher the softening point of the substance (the temp. at which η becomes about 10¹⁰ poise); thus, the steepest slope belongs to the curve of silicate glasses. For each individual curve, a relatively slight temp. dependence is found in regions of low η : as the liquid thickens, that is, with increasing η (decreasing temp.), the slope becomes ever steeper. In the steeper portions of the curves, the curvature is pronounced over temp. intervals other than very narrow ones. There are no discontinuities, and

consequently there is no justification for representing the curves as composed of two intersecting linear portions. Although for certain substances such as metals and fused inorg. salts, data are available only over a relatively short temp. interval, their fragmentary curves do fit into the general picture and appear to prolong those of the other substances. All curves fan out toward higher viscosities and lower temps. Certain substances, such as glucose, silicate glasses, show in the low-temp. region of η less than 10¹⁰ poises, a change of curvature, becoming convex on the side farthest from the $1/T$ axis. On the other hand, viscosity data are available for a series of liquid substances over a temp. interval extending as far as the crit. temp., and also in the gaseous state (e.g. CH₄, C₂H₆, C₃H₈, C₄H₁₀, C₅H₁₂, C₆H₆, C₇H₈, CO, CO₂, CH₃O), or at least over a very wide temp. interval (as for Hg). With these data, the general shape of the $\log \eta$ curve can be constructed in terms of $1/T$, the shape being valid for all substances: at low T , the initial portion of the $\log \eta$ curve of the liquid is concave facing the $1/T$ axis; it then bends over and becomes convex to the $1/T$ axis; the curve of the vapor shows a slow approx. linear rise of $\log \eta$ with T . The two curves meet at the crit. point, where the temp. coeff. of η of the liquid changes its sign. The general shape of the $\log \eta$ ($1/T$) curve for liquids, which is in agreement with the known exptl. partial curves, is not accounted for by existing theories of viscosity of liquids.

The amorphous state. XIX. Temperature dependence of the viscosity of liquids. P. P. Kobeko, S. V. Kuvshinskii and N. I. Shishkin. *J. Tech. Phys. (U.S.S.R.)* 14, 8-9 (1944). The log of viscosity is plotted as a function of temp. for very different substances: ethers, alks., glycerol, org. glasses, H_2O , glass, SiO_2 , molten salts, molten metals, air. All curves have a similar trend; they are flat for low-melting, steep for high-melting products. In a complete system the viscosity curve of the liquid drops (neg. temp. coeff.) to a viscosity of 10^{-1} to 4×10^{-4} poises and, at the crit. temp., reverses to the opposite direction (pos. temp. coeff. of viscosity in a gas). It is believed possible to develop a general theory for all liquids. S. Faksver

Solutions of polymers with linear structure. I. Influence of volumetric thermal expansion on the viscosity of solutions. II. V. Kuvshinskii (Phys.-Tech. Inst., Acad. Sci., Leningrad). *J. Tech. Phys. (U.S.S.R.)* 14, 749-56(1944).—When conclusions on the length and rigidity of polymer molecules are derived from the temp. coeff. of the intrinsic viscosity, this coeff. should be calcd. for a const. vol. concn. (mols. per l. at the test temp.). The coeff. calcd. for a const. wt. concn. c (mols. per kg.) differs increasingly from the correct one, the more the relative viscosity η varies with concn. A convenient equation for c and η is $\log \eta = ac + bc^2$. II. Temperature dependence of viscosity. H. V. Kuvshinskii and N. I. Shikhin. *Ibid.* 757-62.—The relative viscosity of polymer solutions at a const. c and different temps. is expressed by $\log \eta = -\log a + n \log \eta_0$, η_0 being the viscosity of the solvent at the test temp., and a and n constants. From the expts. of K. and S. n is 0.0 for polyisobutylene in spindle oil, 0.041 for butadiene rubber in machine oil (both within the range 0-100°), 0.12 for butadiene rubber in kerosene (from -68° to 25°), 0.13 for 1% polystyrene in toluene (from -83° to 82°), 0.04 for 10% polystyrene in pyridine (from -64° to 48°), and 0.04 for polymethyl methacrylate in acetone (from -68° to 48°). The value of n is smaller, the greater the temp. coeff. of η_0 of the solvent. The temp. coeff. of intrinsic viscosity calcd. for a const. vol. concn. is for these systems 0.0008, -0.0028, -0.0010, -0.0012, 0.0008, and -0.0012, resp. Except for polyisobutylene the polymer length decreases when temp. rises.

Preparation in the flow of solutions of high-molecular compounds. I. A. KIVSHINSKY (Trudy Akademii Vysokomolekulyar. Soedineniyam, Izd. Nauk S.S.S.R., Otdel. Khim. Nauk i Otdel. Fiz. Mat. Nauk, 1943, vol. 1945, 1, 11-12; Chem. Abstr., 1944, 40, 276). Dilute solutions of polymers with molecular weight less than 80,000, and more concentrated solutions of polymers with molecular weight below 15,000, differ from normal solutions

by showing abnormal viscosities and greater relaxation times. These factors cause anomalous effects in the form of gaseous or liquid droplets enclosed in the solutions and flowing with them, or when the solutions flow through narrow openings.

Evaporation of liquids in closed vessels II V. A. Luffe, V. Kuvshinski, and N. M. Melnikov. *J. Tech. Phys. U.S.S.R.* 18, 341-4 (1948). - An equation was derived for the evapn. of a liquid from the bottom of a vertical cylindrical tube originally filled with pure gas. The pressure increased in the 1st stages according to the equation $\Delta B = B - B_0 = 2S_0 B \sqrt{Dt}/V$, where B is the pressure in atm., at beginning of evapn., D is the diffusion coeff. in sq. cm. per sec., t is the time in sec., S is the cross-section of tube in sq. cm. and V is the vol. of tube in cc. This equation is tested for evapn. of benzene in air in a closed vessel, and for CCl_4 in NP_3 . The app. is described and in both cases the evapn. follows the above equation closely in the initial stages. II A

2

Empirical relations between the diffusion coefficients of vapors in different gases. N. V. Kuvshinov, *Russ. Tech. Phys.* 18, 908-14 (1948).—The formula for the diffusion coeff. of a gas s in a gas y ,

$$D_{sy} = B \sqrt{\left(\frac{1}{M_s}\right) + \left(\frac{1}{M_y}\right)} T^{3/2} / (V_s^{1/3} + V_y^{1/3})^2 P$$

(where M = mol. wt., V = mol. vol.), simplified from the gas-kinetic theoretical formula, gives the relatively best agreement with exper. data with $B = 0.0117$, but even so deviations attain 20-30%. If B is given its theoretical value, it is necessary to assume that the kinetic radii r are by 30-100% greater than the radii calcd. from V . An additivity formula of the type $(r_s + r_y) = (r_s + r_z) + A$, with A independent of the nature of x , is confirmed by data for about 40 org. vapors (x) in the pairs $y = \text{CO}_2$, $s = \text{air}$; $y = \text{CO}_2$, $s = \text{H}_2$, and $y = \text{H}_2$, $s = \text{air}$. The sums of the kinetic r of the same pair of substances in different gases differ, with few exceptions, only by a const. Further empirical relations are $D_{12} = 0.183 + 0.65 D_{23}$, $D_{11} = 0.175 D_{22}$, and $D_{33} = 0.003 + D_{22}$, where subscripts 1, 2, and 3 refer to CO_2 , air, and H_2 , resp. These relations permit, for example, the calcn. of D of CCl_4 vapor in air and in CO_2 , when only its D in H_2 is known. They further permit the calcn. of the unknown D of self-diffusion of CO_2 in CO_2 , from the known D of CO_2 in H_2 and D of CO_2 in air, giving the very close values of 0.0225 and 0.0224 cc./sec. Hence, the kinetic radius for CO_2 = 2.2 Å., and, further, from the additivity relations, H_2 = 1.2 and air = 1.6 Å. If these relations are generally valid, and theoretically substantiated, then $D_{12} \approx \sqrt{D_{22} D_{33}}$.

Determination of the coefficients of diffusion of vapors of cyclohexane, chloroform, and acetone, into air. N. A. Goryunova and H. V. Kuvshinskii (Leningrad Phys.-Tech. Inst.). *Zhur. Tekh. Fiz.* 18, 1421-2(1948).—The diffusion coeffs. D were detd. by the 2nd method of Stefan (*Ann. d. Phys. Chem.* 41, 725(1890); Leblanc and Wupperman, *C. I.* 10, 1462) by measurements of the rate of evapn. of the liquid through a long cylindrical tube into air. Under conditions of absence of convection, sufficiently long tube, and zero concn. of the vapors at the open end of the tube, $D = (RT/Mp_a)(L/S)((dg/dt)/\ln p_a/(p_a - p_v))$, where M = mol. wt., p_a = atm. pressure in mm. Hg, L = length, S = cross-section of the tube, dg/dt = wt. rate of evapn. in g./sec., p_v = vapor tension of the liquid. The exact value of the app. const. L/S (32.7 cm.⁻¹) was detd. by measurements with C_2H_6 and Et_2O which gave values in good agreement with accepted data. The results of the measurements are: cyclohexane at 45°, $D = 0.086 \pm 0.013$ cm.²/sec.; $CHCl_3$ at 0° = 0.091 ± 0.012 ; Me_2CO at 0°, $D = 0.100 \pm 0.009$. N. Thon

Kinetics of polymerization of styrene under pressures up to 6000 kg./sq. cm. P. P. Kobeko, B. V. Kuvshinski, and A. S. Semenova (Polytech. Inst., Leningrad). *Zhur. Fiz. Khim.* 24, 515-521 (1950). The contraction due to polymerization of 1 g. styrene was almost independent of the degree of polymerization and of temp. (62-132°) but decreased when pressure P increased from, e.g., 0.21 cc. at 1 kg./sq. cm. to 0.17 cc. at 1000 and 0.11 cc. at 6000 kg./sq. cm. The rate of contraction (that is also the rate of polymerization) was poorly reproducible except in the beginning of every expt. when it was const. (r). This r increased with P more steeply the lower the temp., thus, r at $P = 6000$ was 230 and 65 times that at $P = 1$ at 70° and 127°, resp. The energy V of activation was smaller the greater P . The preponderant factor in the Arrhenius equation was proportional to exp. $(-V/RT)$ as in other reactions at high pressures. I. I. Birkman.

106. Mechanical properties of polymers in the softening region. Elongation diagrams of raw and vulcanised rubbers. N. A. Yezhov and E. V. Kuvshinskiy. *Zhur. Tekh. Fiz.*, 1953, 23, 1343-9; *Chem. Abs.*, 1955, 49, 4320; *Rubb. Chem. Technol.*, 1956, 29, 719-24. Natural rubber and polybutadiene rubber were stretched at temperatures in the range -100° to $+20^{\circ}$ C, and at rates of deformation of 0.05 to 2.5%/sec. From the experimental data curves are constructed for $f=f(\lambda)$ and $\sigma=\sigma(\lambda)$, where $f=F/s_0$ (F =stress, s_0 =cross-section), $\lambda=l/l_0$ (relative extension of the initial length l_0), $\sigma=F/V$. The σ curves are regular for butadiene rubber at temperatures $\theta \geq -42^{\circ}$ C, and they are steeper at lower temperatures; below -42° C a peak appears on the initial part of the curve. Similar peaks are observed in natural rubber and in other plastics. 631371

Title : Type KS Pendulum Elastometer

Orig Pub : Zh. tekhn. fiziki, 1956, 26, No 4, 878 - 886

Abstract : A pendulum elastometer was developed for the study of the elastic properties of rubber at temperatures ranging from 20 -- 120° under the conditions of impact compression lasting for 0.01 -- 0.1 seconds. The instrument permits the tested rubber to be characterized in terms of the magnitude of its rebound elasticity, the magnitude of the dynamic modulus of elasticity, and also the specific mechanical losses referred to the square of the average stress, and the specific mechanical losses referred to the square of the maximum deformation.

TITLE: Measurement of the Mechanical Dynamic Characteristics of Rubbers. (Izmereniye Mekhanicheskikh Dinamicheskikh Kharakteristik Rezin.)

PERIODICAL: Pribory i Tekhnika Eksperimenta, 1957, No.2 , pp. 94 - 98 (USSR).

ABSTRACT: The authors give the description of an instrument similar to that proposed by Marvin, Fitzgerald and Ferry (Ref. 4), but more simple in construction and operation. It can be used to determine, in three independent ways, the dynamic modulus of elasticity and the angle of mechanical losses of rubbers in the frequency range 20-300c/s and in the temperature range -20 to 150°C under the conditions of deformation in axial compression and decompression. The instrument, a cross-section of which is given in Figure 1, uses a vibration generator type GKK-1 (ГКК-1), the necessary temperature being obtained by forcing either water or ethyl alcohol through the envelope for for temperature range -10°C to 100°C. An electrical oven was used for temperatures above 100°C and the instrument was cooled by liquid nitrogen below -10°C. The temperature of the sample was measured by a constantan copper thermocouple with accuracy of 0.5°C. Differing from the

Card 1/2

installation proposed by Marvin, Fitzgerald and Ferry,
two simpler bridge configurations were used (Figures 2
and 3). The determination of the mechanical properties of
the material as based on the Kelvin-Voigt model is also
discussed. The cross sections of the instrument, two
circuit diagrams of the two bridges, three graphs, two
tables of numerical results and the equivalent electrical
circuit diagram of the Kelvin-Voigt model are given.

 TITLE: Determination of the Dynamic Mechanical Characteristics of Rubbers at Acoustic Frequencies (Opredeleniye mekhanicheskikh dinamicheskikh kharakteristik rezin v zvukovom diapazone chastot)
 PERIODICAL: Pribory i Tekhnika Eksperimenta, 1969, No. 5, pp. 86 - 91 (USSR).

ABSTRACT: An installation has been developed for measuring the dynamic modulus of elasticity and mechanical loss angle within the frequency range 80 - 4 000 c.p.s. at temperatures from -20 to +120 °C under conditions of small displacement. Fig. 1 shows the main features in a block diagram, viz, the use of a capacitive pickoff for measuring displacement, the measurement of current in the moving coil as an indication of force, the use of a phasemeter to measure the angle between force and displacement. Fig. 2 is a cross-section through the complete assembly. The material to be tested is indicated as a number of isolators supporting a former made from walrus ivory (s.g. 1.95; $E = 1.3 \times 10^{11}$ dynes/cm²) in the gap of a large electro-magnet. The former carries an exciting coil fed from an audio-oscillator type 3Г-10. A micrometer enables a capacitive pick-off to be positioned under the moving system. The circuit which

Card1/4

Determination of the Dynamic Mechanical Characteristics of Rubbers at Acoustic Frequencies.

converts the changes in capacitance into voltage has been described in principle (Ref.5) and also a practical version of the same (Ref.6). The conversion is linear with an error of less than 3% and gives a sensitivity (including the pre-amplifier) of 10^5 V/mm when the gap between the plates of the capacitor is 0.1 mm. The phasemeter is of the switching type described by Eorman (Ref.9). It works best with an input in each channel of 20 V, a deviation of ± 3 V producing an error of less than 0.1%. The use of voltmeters at the appropriate points in the circuit guarantees a deviation of less than ± 1 V. The supply voltages are stabilized by ferro-resonant and electronic stabilizers. The main electro-magnet supply is separately stabilized at 76 ± 0.1 mA. It is shown from the theory of the measurement that unless the size of the sample is chosen appropriately to the frequency and material constants, appreciable corrections are required. For example, when the magnitude of the elastic modulus is 5×10^7 dynes/cm², the frequency is 1 kc/s and the thickness of the sample is 0.1 cm, the correction is almost 15%. The experimentally determined relation between phase (force-displacement) and frequency differs from theory as noted by

Card2/4

120-5-21/35

Determination of the Dynamic Mechanical Characteristics of Rubbers
at Acoustic Frequencies.

nearly all other authors using electro-dynamic methods. This topic is to be the subject of a separate article. Measurements were discontinued whenever the error exceeded 10%. Fig. 4 shows the variation of modulus and angle of loss ($\tan \delta$) with frequency for a natural rubber at temperatures of -10°C and 75°C . The shape factor of the sample, D (thickness divided by cross-sectional area) was $1/40\text{ cm}^{-1}$. The error in measuring the modulus and loss angle reached 25% at twice the frequency of mechanical resonance. Measurements were made on CKC-30A sulphur-vulcanized rubber by the present method and by two other methods; the "travelling-wave" and "force and velocity" methods. The table and Fig. 5 show that the agreement is quite satisfactory. The maximum force exerted by the vibrator was 5×10^7 dynes at a coil current of 0.5 A. The flux density in the gap was 11 000 gauss and the moving mass was 13.8 g. The minimum recorded displacement was 10^{-5} cm and the minimum angle between force and displacement 1° . The least measured $\tan \delta$ was 0.02. The upper limit of hardness was 2×10^9 dynes/cm. The lower limit of frequency was set by the phasemeter and card 3/4 could be reduced to 0.01 c.p.s. by using an H ϕ -2 in conjunction

TITLE: A "Reochord" Extensometer for the Determination of the Expansion of Rubber in Stretching Tests (Reokhordnyy ekstensometr dlya opredeleniya udlineniya rezin pri ispytaniyakh na rastyazheniye)

PERIODICAL: Pribory i Tekhnika Eksperimenta, 1957, No.5, pp. 122-123 (USSR).

ABSTRACT: The principle of the extensometer and its construction is shown in Fig. 1. The specimen 1 is kept in position by means of the four knife edges 2. The knife edges are pressed against the specimens by means of a rubber band 5. Two blocks 3 made from electrically insulating material are placed on the ends of each of the knife edge carrying carriages. Nichrome wires 4 are let through holes in these blocks and are kept parallel to the direction of extension of the specimen. The resistance between the points A, B and C, D on the wires are measured by means of the DC bridge also shown on Fig.1. The off-balance current can be exhibited on the screen of a magneto-electric oscillograph, type MFO-2. A typical oscillogram is shown in Fig.2 and corresponds to a deformation at a rate of 100% per sec. in an extension-compression cycle. The extensometer may be used in the measurement of expansion when the rates of

TITLE: A Device for Studying Thermoelastic Properties of Adiabatically-stressed Rubber (Ustanovka dlya izucheniya termouprugikh svoystv rezin v adiabaticheskikh usloviyakh rastyazheniya)

PERIODICAL: Pribory i Tekhnika Eksperimenta, 1957, No.6, pp. 92 - 94 (USSR).

ABSTRACT: Two devices are described which can be used to study thermoelastic properties and "crystallisation" processes in resins using the method of adiabatic extension in the temperature range -20 to +100 °C and at different speeds of deformation. The first apparatus is shown in Fig.1 and the second in Fig.2. The aim of the present work was to eliminate, as far as possible, heat losses, and to increase the accuracy of temperature measurement during the process of deformation. It was established that thermal losses are mainly due to convection. They are particularly large at low speeds of deformation, i.e. when the duration of the process is up to 100 to 125 sec. Heat losses in the first device were eliminated by using a vacuum chamber evacuated to a pressure of 10⁻² to 10⁻³ mm Hg. The elimination of heat losses meant that specimens with larger cross-sections could be used (100 mm²). Manganin-constantan

Card1/3

120-6-23/26

A Device for Studying Thermoelastic Properties of Adiabatically-stressed Rubber.

thermocouples were used to measure the temperature. Since the thermal conductivity of manganin-constantan is lower by a factor of 15 than that of copper, the heat losses due to this source were also lowered (the diameter of the wires was 0.05 mm). These measures made it possible to lower the heat losses to 8%. In the second apparatus, it was not necessary to use a vacuum chamber and specimens of high area of cross-sections since in these experiments the duration of deformation was only 1.5 to 6 sec. The general heat losses at the end of a cycle calculated from cooling curves of extended specimens, did not in this case exceed 3 to 4%. The two devices are shown in Figs. 1 and 2. The extensions were measured by transforming them into electrical impulses using the off-balance current of a bridge. A similar scheme was used for the measurement of the stress. The mechanical work performed on the specimen could be estimated to an accuracy $\pm 8\%$. The apparatus was used to study deformation of resins and the results were reported by the present author in Refs. 8 to 10. There are 3 diagrams and 10 references, 5 of which are Slavic.

XII "On the Qualities of Polymeric Glass and the Mechanics of Glass Formation of High Molecular Combinations"

Inter-vuz Scientific Conference (Mezhvuzovskiy nauchnyye Konferentsii)

Vestnik Vysshey shkoly, 1957, # 9, pp. 73 - 76 * (USSR)

Abst: In January 1957, the Second All-Union Conference on Photosynthesis took place, organised by the Institute of Plant Physiology of the Academy of Sciences, USSR, and by the Faculty of Soil-Biology of the Moscow University. About 700 representatives of 130 scientific-research institutes, vuzes and ministries were present. The introductory report was made by Academician A. L. Kursanov who described the development of photosynthesis during the last ten years and invited the scientists to concentrate their work on the application of radioactive and stable isotopes. Nearly 100 reports were read: 13 on photochemistry, 2 on the investigation of chloroplast structure, 12 on the investigation of pigments, 9 on the photosynthesis of water plants, bacteria, etc.

ABSTRACT:

From smoked sheets and from synthetic polyisopren - butadien + sodium -,
divenyl - styrol and divenyl - nitril caotchoucs a series of crude
rubber samples was prepared, which differed in their degree of vul-
canization. In order to obtain this effect, the contents of sulphur
and of catalyzer substance varied as well as temperature and the time
of vulcanisation. The dependence of the dynamic characteristics of
rubber samples with different degrees of vulcanization can be ex-
plained on the basis if these investigations in the following way:
The chains of the vulcanized substance are interconnected by firm
chemical and somewhat weaker physical bindings thus forming a net-
work. With increasing temperature the number and rigidity of the lat-
ter decreases considerably. The bounce-elasticity, on the other hand,
increases, at the expence of increase of the flexibility of the
chains, whereas a rise in temperature leads to a weakening and reduction
of the number of physical bindings, which implies a reduction of the
total number of chained domains which give the network its elasticity,
and produces an increase of the number of chains which have lost their

connection with the network except at one end. Those chains slow down the motion of the elastic elements and diminish elasticity. In the same way the change of the dynamic Young's modulus with temperature can be explained. The properties of crude rubber samples originating from the same raw material are determined by the density of the vulcanizing network. A control of the conditionally balanced modulus makes it possible to obtain rubber with different characteristics which can be determined beforehand by means of the variation of recipes and of the conditions of vulcanization. The entire test takes only 20 min. (With 7 illustrations, 1 table and 4 citations from Slav publications).

TITLE: Influence of Rubber Molecular Weight on its Mechanic Properties.
(Vliyaniye molekulyarnogo vesa kauchuka na dinamicheskiye
mekhanicheskiye svoystva rezin, Russian)
PERIODICAL: Zhurnal Tekhn. Fiz. 1957, Vol 27, Nr 5, pp 1019-1028 (U.S.S.R.)

ABSTRACT: At temperatures of 20, 60 and 100° C the modifications of the elasticity modulus and of the rebounding of rubber of fractions of divinylstyrol caoutchouc SKS-30-A were investigated in an interval of molecular weights of 45 000 to 620 000 with different vulcanization depths (in the case of a modification of the conditionally balances modulus from 5 to 70 kg/qcm). The dynamic elasticity modulus at room- as well as at increased temperature depends only little on the molecular weight of the initial caoutchouc. At higher temperatures the elasticity of rubber is mainly determined by the depth of vulcanization. As a measure the conditional balanced modulus may serve. At low temperatures (20° C) elasticity grows with the depth of vulcanization, but in the case of rubbers made from fractions of different molecular weights this growth differs as to extent. At 20° C the increase of vulcanization depth increases the elasticity of rubbers of low

molecular fractions (45 000) less than in the case of those of high molecular fractions (more than 133 000). The amount of maximum elasticity of rubbers obtained from caoutchoucs of the same molecular weights does not depend on the character of the accelerator used. (With 5 Tables, 6 Illustrations, and 7 Slavic References).

TITLE: Thermoelastic Phenomena in Synthetic Rubbers at Adiabatic Deformation Reaching the Break (Termouprugiye yavleniya v rezinakh iz SKS-30A i SKB pri adiabaticheskom deformirovani do razryva).

PERIODICAL: Zhurnal Tekhn. Fiz., 1957, Vol. 27, Nr 10, pp. 2303-2306 (USSR).

ABSTRACT: On the strength of the investigations given here following can be said. 1) The expansion of the vulcanisates SKS-30A and SKB reaching the break is accompanied by a heat development equivalent to the tension work, a fact which points out the kinetic nature of the elastic forces in these vulcanisates. 2) An alteration of the vulcanization process of a mixture and the introduction of a filler leads only to an alteration of the rubber elasticity modulus. The correspondances to a rule in the transformation of work into heat are not affected with it. The lacking of the crystallization processes even in important tensions ($\lambda \approx 6 \div 7,5$) is obviously determined in the first place by the irregular construction of the hydrocarbon skeleton of the final caoutchoucs. 3) In the case of rubbers with active fillers which were obtained under optimum conditions by vulcaniza-
